12. Sponsoring Organization Name and Address NOAA, National Marine Fisheries Service Washington, DC 20235		13. Type of Report & Period Covered Completion Report June 1968 - August 1970	
15. Supplementary Notes New Jersey Department of Environmental Protection Completion Report for period June 1968 to August 1970. Released July 1971.		14.	
16. Abstracts The inventory was accomplished in two phases. Phase I of the 1969 - 1970 Estuarine Inventory consisted of a survey of the fishes of the Great Bay - Mullica River System and, to a lesser extent, the Maurice and Manasquan Rivers. The object was to determine what species of finfish utilize the estuarine waters of New Jersey. The second phase mapped and described the physical - chemical attributes of the estuary. Monthly sampling surveys recorded conditions from 1968 into August 1970. (Sinha, OEIS)

PHASE I - FISH STUDY
John F. McClain, Jr.

INTRODUCTION

Phase I of the 1969-1970 Estuarine Inventory consisted of a survey of the fishes of the Great Bay-Mullica River System and, to a lesser extent, the Maurice and Manasquan Rivers. The object was to determine what species of finfish, at some stage in their life cycle, utilize our estuarine waters.

ACKNOWLEDGEMENTS

Ronald White initiated this Phase of the project and was of great assistance to me when I took over. Paul Hamer and Walter Murawski contributed their knowledge. Ted Metzger, Harry Bustard, James Leonard and Russell Tilton assisted with the field work. Ted Metzger also assisted in the analysis of the data. Ottawa Pullen sorted and identified the plankton. John Nakai collected the May and June plankton samples.

METHODS AND MATERIALS

All sampling was done with a 300-foot bag seine, ten feet deep. The dimensions are as follows: top line 3/16" nylon with 3 x 1 1/2" sponges floats every 18 inches; bottom line double 1/4" nylon with #9 leads every 18 inches; outer wings each 75 feet long 1" stretch mesh Style #4; inner wings each 55 feet long 5/8" stretch mesh Style #4; 15 feet on each side of bag 3/8" stretch mesh Style #4; bag 10' x 10' 3/8" stretch mesh Style #4. The seine was set from a 17' Boston whaler.

Five seining stations were utilized in the Mullica River-Great Bay Estuary, three in the Manasquan River and three in the

Maurice River (see Figures 1, 2 and 3 for specific locations). The stations were sampled monthly when possible. Data was collected as follows: the catch was speciated, each species was weighed, measured, and counted if numbers allowed. Aliquot samples were taken when individual numbers of any species were so great as to make processing the entire catch impractical. The subsamples were counted and measured and the data adjusted accordingly. Surface water temperatures were taken at each station with a pocket thermometer. Water samples were taken and salinities were run at the laboratory by John Makai on a wide range salinity hydrometer. Weather conditions also were recorded.

Plankton samples were taken at six stations - four in Great Bay and two in the Mullica River (see Figure 1 for specific locations). A plankton net rig, revised from one used by Dovel as reported in Chesapeake Science, Vol. 5, No. 1-2, pp. 77-90, Mar.-June 1964, was constructed. It is designed to fish two one-meter plankton nets simultaneously, one at the surface and one at the bottom. Instead of the large concrete weight and cable used by Dovel for his deep water work, two six pound grappling hooks attached to six feet of heavy chain and 5/16" polypropylene line were used. In addition to these modifications, a lighted staff buoy was added for night work.

CM₂-T.S.K. Flowmeters were on order but arrived too late to be used.

RESULTS AND DISCUSSION

Seining - Great Bay-Mullica River

Sixty species of finfish were taken during the sampling

period. A list of the species taken including scientific and common names is shown in Table 1.

Results by Station:

Little Beach. This station is a sandy beach located just inside Little Egg Inlet on the southern shore. The bottom is hard sand. It is seinable at all tidal stages. Thirty-one species of fish were taken at this station (see Table 2). Silversides were the most abundant, over 24,000 being taken, followed by bay anchovy 4941, striped killifish 602, and silver perch 571 (see Table 3). Four species, the sand lance, smallmouth flounder, sheepshead minnow and permit were taken exclusively at this station. The last two species were taken once (Table 2).

The temperature during sampling operations ranged from 46°F. in November to 77°F. in August, and the salinity from 25 ‰ in May to 31.8 ‰ in June and October (Table 4).

Cape Horn. This station is located on the north side of Great Bay. It consists of a peat bank covered with saltwater cordgrass with a drop of about 4 feet. The bottom is primarily peat pieces, detritus and mud. The station was seined at or near high tide to minimize difficulties caused by the near vertical bank and irregular terrain.

Thirty-one species of fish were taken at this station. The bay anchovy was the most abundant, over 13,000 appearing in the samples. Silversides were second in number - 6298, and silver perch third with 581 fish taken. Again silversides were taken in every sample. The northern pipefish, northern puffer and the winter flounder were also common fishes at this station. Two species were taken only at this station: two red hake, one in June 1969 and one in May 1970. and one black sea bass in July 1969.

Temperatures during sampling ranged from 40° F. in March to 74° F. in June and August; salinities from 24 ‰ in May to 31.9 ‰ in July.

Graveling Point. This station is located on the north shore of Great Bay approximately 1.2 nautical miles below the river mouth. It is composed of sand and mud. It was originally seinable at all except low water. In March we found an oyster stake infringing on the seining area. We were able to continue using the site by seining at high tide.

Twenty-four species of fish were taken. Again the bay anchovy was the most abundant (over 11,000), followed by silversides (6800), and the silver perch (1261). Other common species were the striped killifish, northern puffer, oystertoadfish and winter flounder.

The temperature when hauls were made ranged from 47° F. in November and March to 78° F. in August. The salinity ranged from 19 ‰ in August to 28.9 ‰ in June.

Landing Creek. This station is located on the southern side of Great Bay approximately 2.4 nautical miles below the river mouth. Physically it is similar to Cape Horn, with the exception of a two foot drop off the bank. The bottom is very irregular and covered with large pieces of peat. It was seinable from two hours before high tide until two hours after.

The greatest number of species was taken at this station (33), as well as the most fish (over 44,000). The bay anchovy again heads the list (over 40,000), followed by the silversides (1218), the silver perch (932) and the oystertoadfish (173). Other common fish were the northern pipefish, Atlantic needlefish and the mummichog.

For seven of the 33 species, the catch at Landing Creek constituted over 40% of the total number of these species taken throughout the year.

The temperature while sampling ranged from 38° F. in March to 76° F. in August, and the salinity from 13.8 ‰ in May to 27.5‰ in July and October.

Lower Bank. This station is located at river mile 14 on the northern bank of the Mullica River just downstream of the county highway bridge. The bottom is mostly gravel with some mud and a few waterlogged stumps and branches. The station is a spit of land projecting downstream. It was not seizable at high tide as it was completely covered by water.

Thirty species were taken at this station. The four most abundant species were the bay anchovy (4500), alewife (883), white perch (326) and golden shiner (212). Other common species included the brown bullhead, yellow perch, white sucker and banded killifish.

The temperatures encountered during sampling ranged from 36° F. in December to 77° F. in June, and the salinities from < 1 ‰ in December to 4.7 ‰ in September.

Monthly Results:

June was the first sampling month of the project year. All stations were sampled. The temperature ranged from 70° F. to 77° F. and the salinity from 3.8 ‰ to 31.8 ‰. Twenty-four species were taken, numbering over 23,000 (see Table 5). Of these, 95% were bay anchovies, 3% silversides and 2% other. Most abundant of the latter was the alewife (92 fish), followed by the northern puffer (75), the bluefish (21) and the winter flounder (18) (see Table 6).

In July 37 species were taken, the greatest number for any one month. However, the number of individual fish was the lowest of the summer months. The reason was the lack of large numbers of bay anchovies and silversides. These species numbered only 5825 fish in July as opposed to 22,005 in June, 14,302 in August, 50,531 in September, and 20,152 in October. Excluding these two, July's catch was the third largest of the year. Three species were taken only in July: sea bass, sheepshead minnow and the smooth dogfish (Table 5). Some of the more numerous species were the Atlantic needlefish, 32% of the year's catch, banded killifish 46%, bluefish 58%, hogchoker 96%, sennet 96%, striped killifish 78%, white perch 49%, and winter flounder 40% of the year's catch. The temperature ranged from 72° F. to 76° F. and the salinity <1 ‰ to 31.9 ‰.

August's sampling resulted in 16,000 fish comprising 34 species. Again the majority were bay anchovies and silversides. Excluding these species results in the highest monthly catch of the year, 2302 fish. The highest temperatures were recorded this month also, ranging from 74° to 78° F. The salinity ranged from 1 ‰ to 27 ‰. Two species made their only appearance of the year, the black cruppy at Lower Bank and the spot at Landing Creek and Little Beach. The alewife and the brown bullhead reached their highest numbers in August (440 and 126 respectively). Other common species were the silver perch, striped killifish, white perch, golden shiner, northern puffer and Atlantic needlefish.

September's catch numbered 52,600 fish, 45,000 of which were bay anchovies and 5,400 silversides. Three other species also appeared in large numbers - silver perch 1377, striped anchovy 350,

and oyster toadfish 161. Silver perch were taken at all four bay stations.

Oyster toadfish were taken at all bay stations except Little Beach where it was never taken. Also, this was the only month oyster toadfish were taken at Lower Bank. The temperature at Lower Bank was 64° F. and the salinity 47 ‰. All striped anchovies were taken at Landing Creek (temperature 64° F. and salinity 25 ‰).

Thirty-three species numbering 21,000 fish were taken in October. Ninety-six percent were either bay anchovies or silversides. The other 4% consisted primarily of alewives 310, silver perch 148, and Atlantic menhaden 144. The alewives were taken at Lower Bank in 68° F. water with a salinity of 3.8 ‰. Sixty-two were measured and ranged from 8 to 12 cm. One hundred and forty menhaden were taken at Landing Creek. Water temperature was 68° F. and salinity 27.6 ‰. Thirty-five were measured and ranged from 10 to 19 cms. The other 4 menhaden were taken at Lower Bank. Seventy-one silver perch were taken at Cape Horn (water temperature 65° F. and salinity 30.8 ‰), 23 at Graveling Point (62° F. and 24.9 ‰), and 54 at Landing Creek (68° F. and 28 ‰). Temperatures at the sampling stations ranged from 62° F. to 68° F., and salinity from 3.8 ‰ to 30.8 ‰.

Cape Horn was not sampled in November. Twelve species were taken at the remaining four stations. Silversides constituted 81% of the catch. Next in abundance was the golden shiner 10%, followed by the sand lance 3%. Temperatures ranged from 45° F. to 48° F., and salinity from 20.3 ‰ to 25.6 ‰ (no salinity for Lower Bank).

Only Lower Bank was sampled in December. The water tempera-

ture was 36° F. and the salinity ≈ 1 ‰. Seven species were taken numbering 66 fish. The golden shiner constituted 68% of the catch. This was one of the two months that white perch were not taken at Lower Bank.

No sampling was done during January or February because of the weather and ice.

Water temperatures during March ranged from 38° F. to 47° F. and salinity from 1 ‰ to 27.7 ‰. All stations except Little Beach were sampled, with over 300 fish taken. Silversides constituted 66% of the catch, followed by the three-spined stickleback. The only pollock taken during the sampling year was a 3 cm. fry found in a Landing Creek haul on March 10. The water temperature was 38° F. and the salinity 24 ‰.

Graveling Point was not sampled in April or May due to the abundance of striped bass fishermen.

In April the water averaged 10° warmer than in March. The temperature ranged from 45° F. to 57° F., and the salinity from ≤ 1 ‰ to 28.2 ‰. Blueback herring appeared in the Landing Creek sample. It was their first occurrence in any sample since the preceding June. Silversides were the most abundant species, followed by the johnny darter, yellow perch, blueback, golden shiner, and windowpane. Fifteen species were taken for a total of 129 fish.

The temperature in May was 70° F. at Lower Bank and 57° F. at Landing Creek, an increase of 18° F. and 12° F. over April. No temperature was taken at Little Beach or Cape Horn because of a broken thermometer. However, the temperature at the Fish Factory, which is approximately half way between the latter two stations, was 64° F. on the sampling day. This rise in temperature is reflected in the number

of species (28) and individuals (1721) taken. Bay anchovies and silversides made up 47% of the catch, followed by sea herring 29%, mummichog 6%, and white perch 5%.

The bay anchovy was the most abundant species, constituting 61% of the 124,000 fish taken. It was taken at all stations in salinities ranging from 2 ‰ to 32 ‰, and temperatures from 38° to 77° F. Next in abundance were the silversides, making up 32% of the catch. They were taken at all stations in all sampling months except December. Salinities ranged from <1 ‰ to 30 ‰, and temperatures from 38° to 78° F. Third was the silver perch, 3% of the catch. It was taken at all bay stations. The known salinities ranged from 18 ‰ to 31 ‰ and the known temperatures from 48° F. to 78° F. Tables 7 and 8 give the salinity and temperature ranges of some common species. Length frequencies of 10 common species are given in Tables 9 through 15.

Seining - Manasquan River.

Three stations were seined in the Manasquan River during June, July and August 1969, and April and May 1970. Forty-six species totalling 28,600 individuals were taken. A list of the species including common and scientific names is given in Table 16. The results are summarized in Table 17. Following is a brief description of each station and the results. For specific locations, see Figure 2.

Inlet. This station is located on the north shore of the Manasquan River approximately 500 yards upstream from the Coast Guard Station. The bottom is sand and the depth at mean-low water is ten feet. Over 20,000 fish were taken at this station; 18,900 were silversides (see Table 17). Other common species were the northern puffer,

the winter flounder and the bluefish. The temperatures ranged from 45° F. in April to 75° F. in July, and salinity from 18.5 ‰ in June to 32 ‰ in July (Table 18).

Osborn Island. This station is located on the western side of Osborn Island 2½ nautical miles above the inlet. The bottom is sand and the depth at mean low water is six feet. Silversides were the most numerous species - 1328 fish, followed by winter flounder, weakfish and bay anchovy. Temperatures ranged from 49° F. in April to 76° F. in August and salinities from 29 ‰ to 29.8 ‰.

Bluffs. This station is located on the northern bank at the upper end of the river approximately 5.1 nautical miles from the mouth. The bottom is stones and gravel and the depth at mean low water about three feet. This station was accessible only at high water. During April and May a 60-foot bag seine was used for sampling. Nineteen species, numbering over 2500 individuals, were taken. The bay anchovy was the most numerous, 1069 fish. Silversides numbered 628, the lowest number of the three stations.

Overall, silversides and bay anchovies made up 86% of the catch.

Seining - Maurice River.

Thirty-four species of finfish were taken during the sampling period. A list of the species taken is given in Table 19. Sampling was conducted during June and August 1969 and April and May 1970 at these stations. The results are summarized in Table 20. A brief description of each station and the results follows. For specific locations see Figure 3.

East Point Cove. This station is located in the Maurice River Cove at East Point. The water is approximately six feet at high

tide, which is the only time we seined here. The bottom is sand and mud. The station was surrounded by gill nets in the spring, which may have had some effect on the number of large fish taken with the seine. Twenty-three species were taken numbering 10,800 fish. Most abundant were the silversides - 4642, followed by the bay anchovy - 3276 and the American eel - 1639 (see Table 20). Butterfish, filefish, cusk eel and kingfish were taken only at East Point. Temperatures ranged from 55° F. to 80° F. and salinity from 14 ‰ to 23 ‰ (see Table 21).

Leesburg. This station is located on the eastern bank of the river approximately 6½ nautical miles upstream. It was not seined in April or May due to the presence of large numbers of fishermen. Sixteen species were taken here. The bay anchovy was the most abundant - 44 fish, followed by the hogchoker and silversides.

Yawpshore. This station is located on the eastern bank, 13 miles upstream. The bottom is gravel. Fourteen species, totalling 1031 individuals, were taken. White perch were the most numerous species with 301 fish caught. Next was spottailed shiner 312, hickory shad 166, and bay anchovy 119. The salinity at this station was always less than 1 ‰ when we sampled.

Plankton Sampling - Great Bay-Mullica River Stations

Light "4". This station is located on the inland waterway approximately 200 yards off the Coast Guard Station on the north side of Little Egg Inlet. The depth at mean low water is 22 feet. The strong current made sampling difficult.

Light "20". This station is also on the inland waterway 2.6 nautical miles southwest of Light "4" in the southern half of Great Bay. The depth at mean low water is seven feet, during sampling

about ten feet.

Cape Horn. This station is located approximately 150 yards off Cape Horn on the north shore of Great Bay. The depth at mean low water is 13 feet.

Graveling Point. This station is halfway between Graveling Point and Cape Horn, about 750 yards offshore. The depth at mean low water is ten feet.

French Point R 6. This station is located six miles upstream of the river mouth off French Point. The depth at mean low water is 25 feet.

Lower Bank R 14. This station is located at river mile 14 just downstream of the county highway bridge. The depth at mean low water is seven feet.

Plankton sampling was conducted at night on a flooding tide during June, July, August and October 1969. Sampling in April and May 1970 was done during the day on a flooding tide. The results are summarized in Table 22.

TABLE 1. A list of species taken in the Great Bay-Hullica River Estuary, common and scientific names. June 1969 to May 1970.

Alewife, <u>Alosa pseudoharengus</u>	(Wilson)
American eel, <u>Anguilla rostrata</u>	(LeSueur)
Atlantic menhaden, <u>Brevoortia tyrannus</u>	(Latrobe)
Atlantic needlefish, <u>Strongylura marina</u>	(Walbaum)
Banded killifish, <u>Fundulus diaphanus</u>	(LeSueur)
Bay anchovy, <u>Anchoa mitchilli</u>	(Valenciennes)
Black crappie, <u>Pomoxis nigromaculatus</u>	(LeSueur)
Blueback herring, <u>Alosa aestivalis</u>	(Mitchill)
Bluefish, <u>Pomatomus saltatrix</u>	(Linnaeus)
Bluegill, <u>Lepomis macrochirus</u>	Rafinesque
Brown bullhead, <u>Ictalurus nebulosus</u>	(LeSueur)
Chain pickerel, <u>Esox niger</u>	LeSueur
Crevalle, <u>Caranx hippos</u>	(Linnaeus)
Cunner, <u>Tautoglabrus adspersus</u>	(Walbaum)
Fusiform darter, <u>Etheostoma fusiforme</u>	(Girard)
Four-spined stickleback, <u>Apeltes quadracus</u>	(Mitchill)
Golden shiner, <u>Notemigonus crysoleucas</u>	(Mitchill)
Hickory shad, <u>Alosa mediocris</u>	(Mitchill)
Hogchoker, <u>Trinectes maculatus</u>	(Bloch and Schneider)
Johnny darter, <u>Etheostoma nigrum</u>	Rafinesque
N. Kingfish, <u>Menticirrhus saxatilis</u>	(Bloch and Schneider)
*Mullet, <u>Mugil</u>	sp.
Mummichog, <u>Fundulus heteroclitus</u>	(Linnaeus)
Naked goby, <u>Gobiosoma boscii</u>	(Lacépède)
Northern pipefish, <u>Syngnathus fuscus</u>	Storer
Northern puffer, <u>Sphaeroides maculatus</u>	(Bloch and Schneider)
Oyster toadfish, <u>Opsanus tau</u>	(Linnaeus)
Permit, <u>Trachinotus falcatus</u>	(Linnaeus)
Pollock, <u>Pollachius virens</u>	(Linnaeus)
Red hake, <u>Urophycis chuss</u>	(Walbaum)
Sand lance, <u>Ammodytes americanus</u>	DeKay
Sea bass, <u>Centropristes striatus</u>	(Linnaeus)
Sea herring, <u>Clupea harengus harengus</u>	(Linnaeus)
Sea horse, <u>Hippocampus hudsonius</u>	DeKay
Sea robin, <u>Prionotus</u>	sp.
Sennet, <u>Sphyræna borealis</u>	DeKay
Sheepshead minnow, <u>Cyprinodon variegatus</u>	(Lacépède)
Silver perch, <u>Bairdiella chrysura</u>	(Lacépède)
**Silversides, <u>Menidia</u>	sp.
Smallmouth flounder, <u>Etropus microstomus</u>	(Gill)
Smooth dogfish, <u>Mustelus canis</u>	(Mitchill)
Spiny boxfish, <u>Chilomycterus schoepfi</u>	(Walbaum)
Spot, <u>Leiostomus xanthurus</u>	Lacépède
Pinfish, <u>Lagodon rhomboides</u>	(Linnaeus)
Spottailed shiner, <u>Notropis hudsonius</u>	(Clinton)
Striped anchovy, <u>Anchoa hepsetus</u>	(Linnaeus)
Striped bass, <u>Morone saxatilis</u>	
Striped killifish, <u>Fundulus majalis</u>	(Walbaum)
Striped mullet, <u>Mugil cephalus</u>	(Linnaeus)

TABLE 1. (Continued)

Summer flounder, Paralichthys dentatus (Linnaeus)
 Sunfish, Lepomis gibbosus (Linnaeus)
 Tautog, Tautoga onitis (Linnaeus)
 Three-spined stickleback, Gasterosteus aculeatus Linnaeus;
 Weakfish, Cynoscion regalis (Bloch and Schneider)
 White catfish, Ictalurus catus (Linnaeus)
 White mullet, Mugil curema Valenciennes
 White perch, Morone americanus
 White sucker, Catostomus commersoni (Lacépède)
 Windowpane, Scophthalmus aquosus (Mitchill)
 Winter flounder, Pseudopleuronectes americanus (Walbaum)
 Yellow perch, Perca flavescens (Mitchill)

* Mullet - Thirteen mullet were identified as to species -
 two striped mullet and 11 white mullet. Twenty-two
 were not speciated.

** Silversides - Three species involved: Menidia menidia,
Menidia beryllina, and Membras vagrans. These
 fishes will be speciated in following surveys.

TABLE 16. A list of species taken in the Manasquan River.

Alewife, Alosa pseudoharengus (Wilson)
 American eel, Anguilla rostrata (LeSueur)
 Atlantic menhaden, Brevoortia tyrannus (Latrobe)
 Atlantic needlefish, Strongylura marina (Walbaum)
 Atlantic sea herring, Clupea harengus harengus (Linnaeus)
 Banded killifish, Fundulus diaphanus (LeSueur)
 Bay anchovy, Anchoa mitchilli (Valenciennes)
 Blueback herring, Alosa aestivalis (Mitchill)
 Bluefish, Pomatomus saltatrix (Linnaeus)
 Bluegill, Lepomis macrochirus Rafinesque
 Butterfish, Poronotus triacanthus (Peck)
 Chub mackerel, Scomber colias Gmelin
 Common filefish, Monacanthus hispidus (Linnaeus)
 Coronet fish, Fistularia tabacaria
 Crevalle (jack), Caranx hippos (Linnaeus)
 Cunner, Tautogolabrus adspersus (Walbaum)
 Grubby sculpin, Myoxocephalus aeneus (Mitchill)
 Hickory shad, Alosa mediocris (Mitchill)
 Northern Kingfish, Pentaceros saxatilis (Bloch and Schneider)
 Longhorn sculpin, Myoxocephalus octodecempinosus (Mitchill)
 Lookdown, Selene vomer (Linnaeus)
 Mullet, Mugil sp.
 Mummichog, Fundulus heteroclitus (Linnaeus)
 Naked goby, Gobiosoma bosci (Lacépède)
 Northern pipefish, Syngnathus fuscus (Storer)
 Northern puffer, Sphaeroides maculatus (Bloch and Schneider)
 Oyster toadfish, Opsanus tau (Linnaeus)
 Permit (red pompano), Trachinotus falcatus (Linnaeus)
 Oceanpout, Macrozoarces americanus (Bloch and Schneider)
 Red hake, Urophycis chuss (Walbaum)
 Sand lance, Ammodytes americanus (DeKay)
 Black sea bass, Centropristes striatus (Linnaeus)
 Sea robin, Prionotus sp.
 Sennet, Sphyraena borealis (DeKay)
 Silver perch, Bairdiella chrysura (Lacépède)
 Silversides, Menidia sp.
 Striped anchovy, Anchoa hepsetus (Linnaeus)
 Striped bass, Morone saxatilis
 Striped killifish, Fundulus majalis (Walbaum)
 Summer flounder, Paralichthys dentatus (Linnaeus)
 Tautog, Tautoga onitis (Linnaeus)
 Warsaw grouper, Epinephelus nigritus (Holbrook)
 Weakfish, Cynoscion regalis (Bloch and Schneider)
 White perch, Morone americanus
 Windowpane, Scophthalmus aquosus (Mitchill)
 Winter flounder, Pseudopleuronectes americanus (Walbaum)
 Blue crab

PHASE II
PHYSICAL-CHEMICAL STUDIES

John F. Makai
Phase Leader

INTRODUCTION

It was the objective of this Phase to map and/or describe the physical-chemical attributes of the Mullica-Great Bay Estuary. Monthly sampling surveys were established to record conditions on a yearly basis. However, this particular study extended from 1968 into the 1970 year.

ACKNOWLEDGMENTS

Phase leader would like to thank the cooperation and guidance from Dr. James Durand and Mr. R. Nadeau of Rutgers University along with Paul Hamer and Walter Murawski. Appreciation also is extended to the Soils and Conservation Offices of Burlington, Atlantic and Ocean Counties. In connection with the field work, thanks to Fishery Workers Russell Tilton, James Leonard, Harry Bustard, Tom Dempsey, and help with some laboratory work, Robert Weaver. A special thanks goes out to Fishery Worker Ferdinand Metzger who not only helped with some field work but also with the preparation of some charts and graphs for this report.

DESCRIPTION OF THE AREA

The length of the survey area of the Mullica-Great Bay Estuary extending from Little Egg Inlet to the Green Bank Bridge (river mile 17) is approximately 16.02 miles. The maximum width of the bay extending from the northeast shore (near Cape Horn) to the southwestern portion (Landing Creek) is 4.3 miles. The total acreage for the estuarine system sampled was 52,068.17 acres in-

cluding part of the Brigantine National Wildlife Refuge and both the Bass and Wading Rivers. From this total acreage, Brigantine Refuge consists of 13,434 acres of salt marsh, 4,390 acres of water and 1,561 acres of upland. The remainder of marshland in this estuary is approximately 18,741.96 acres. Water acreage of Great Bay is 9,138.65 acres, and the Mullica River is 3,850.32 acres. The two main tributaries affecting the estuary are the Bass and Wading Rivers with 285.58 and 666.66 water acres, respectively.

About 62% of total acreage is composed of tidal marsh. Marshland consists of organic silt subject to daily flooding on flats extensively found along the Mullica and Wading Rivers. The tide is of the semi-diurnal type; there are two flood tides and two ebb tides in a normal day. A grass cover of salt-tolerant grasses occurs on this soil. Salt hay was formerly harvested but is not now. Methane, or marsh gas, forms in the soil.

The estuary has been extensively ditched by the New Jersey Mosquito Commission to reduce the breeding areas of the mosquito. Some dredging has been done in the Mullica and Wading Rivers to provide a channel for small pleasure boats. All dredged material was disposed of by pumping into diked areas of marsh. There is also dredging each year along and in the Intracoastal Waterway located on the southern portion of the bay and Little Egg Inlet which is subject to constant weather erosion. Little Beach, which extends into Little Egg Inlet, is subject to change from year to year.

Charlesworth (1968) (unpublished) states in Great Bay the average fresh water discharge into the bay from the Mullica River is of the magnitude of $312 \text{ ft.}^3/\text{sec.}$ (U.S. Geological Survey 1966). For a complete tidal cycle of $45 \times 10^3 \text{ sec.}$, this amounts to $14.040 \times 10^6 \text{ ft.}^3$, which compared to an estimated mean tide prism of

$1934 \times 10^6 \text{ ft.}^3$ gives a salt water-fresh water ratio of about 133 which is higher than what is considered the dividing ratio (100) between a partially-mixed and well-mixed estuary (Pritchard, in Lauff, 1967). He concluded that the flow is most likely dominated by the tide and there is little vertical stratification of salinity (at least away from the mouth of the Mullica River) and no opposing surface and bottom flow.

Charlesworth also found on the basis of current drogue data analysis of hydrographic charts and aerial photography and observations of * foam lines and ice floes, the ebb current in Great Bay exhibits the following characteristics:

(a) From the area of the mouth of the Mullica River, the flow is dominantly (1) across the bay toward the tidal deltaic complex where it drains centripetally into the numerous channels, and (2) along the southwest part of Great Bay in a broad sweep to Little Beach Channel and the middle ground of inner Little Egg Inlet. This flow is augmented by that issuing from Great and Main Marsh Thoroughfares. Maximum ebb velocities in Great Bay are probably of a magnitude of 1.5 ft/sec., with greater velocities at the mouth of the Mullica River and near the entrance to inner Little Egg Inlet.

(b) The outflow from Little Egg Inlet is of the form of a broad jet with its axis along the Little Egg Inlet gorge, and with maximum velocities perhaps as high as 5.0 ft/sec. The flow is directed towards the southeast with the outer limits of the flow also affected by the coastal current. The juncture of ebb and flood currents.

* The "foam lines" are lines of foam, detrital matter and trash, including lines of intersection between two differently colored masses of water, and zones of shear between two water masses.

issuing from or flowing into Little Egg and Brigantine Inlets is most likely off Little Beach where the six foot contour is close to the beach and the 12 foot contour is indented towards Brigantine Inlet.

The gross ebb flow pattern of Little Egg Inlet is reflected in the broad lobate nature of the offshore contours.

Charlesworth's flood current patterns in this estuary were also determined mainly from drogue data and analysis of hydrographic charts and exhibit the following characteristics:

(a) In Great Bay the stream lines of flow may also be independent of the direction of flow, but it is most likely that the flow across the northeast half of the bay, issuing from the tidal delta complex, is the dominant flow and of greater magnitude than the ebb. The submerged spit at Graveling Point suggests, for example, the dominance of the flood current along this part of the north side of the bay. Flow through the middle ground and Little Beach Channel at inner Little Egg Inlet enters the lagoon behind Little Beach spit, Great Thorofare, Little Bay via Main Marsh Thorofare, and the southwest side of Great Bay. Maximum flood current velocities in Great Bay are probably around 1.5 ft./sec. with higher velocities at inner Little Egg Inlet and the entrances to the Mullica River and Main Marsh Thorofare.

(b) The flood pattern in Little Egg Inlet is markedly different from the ebb pattern. The flow is of the form of an asymmetric tidal drain with the greater flow coming from an upcoast, or northeast direction. In Little Egg Inlet the flood current, unlike the ebb, does not conform to the bottom topography but flows directly to Shooting Thorofare and inner Little Egg Inlet. Along

Little Beach the flood current conforms to the topography of the shoals, and the line of divergence of Little Egg Inlet and Brigantine Inlet flood currents is off south Little Beach.

In outer Little Egg Inlet the flood velocities are perhaps as high as 5.0 ft./sec. In inner Little Egg Inlet, flood currents attain velocities of at least 5.0 to 5.5 ft./sec.

In the Mullica River Basin, there are gaging stations located on the Mullica River near Batsto, on the Batsto River at Batsto, and on the Oswego River at Harrisville, to measure the amount of river discharge daily. The Mullica and Oswego Rivers are occasionally regulated by ponds and cranberry bogs located upstream. No data will be presented in this report concerning river discharge from these three gaging stations except what was quoted from Charlesworth.

Figures 1 and 2 represent bottom profiles of the estuary at certain points and locations of these areas can be seen in Figure 3.

METHODS AND PROCEDURES

Laboratory Equipment: Since dissolved oxygen and salinity analyses were to be done in rather large quantities, two 50 ml. automatic burets were set up connected to two four-liter aspirator bottles elevated close to the ceiling. An electric magnetic stirring motor was purchased to produce a uniform agitation action in analysis.

The Twelfth Edition of Standard Methods for the Examination of Water and Wastewater is being used as the source for most of the chemical analyses being run.

The following analytical procedures are being used:

Dissolved Oxygen (ppm.) - Determinations are based on the Winkler Method with an Azide Modification of Iodometric Method. The standard 300 ml. BOD bottles are being used as sampling bottles.

Salinity ($^{\circ}/_{\text{oo}}$) - Determinations are based on two procedures: (i) all hydro-run samples are analyzed according to the Knudsen Method; (ii) all transect and nutrient sampling are analyzed according to wide range salinity Hydrometers.

Turbidity (units) - Determinations are based on the Jackson Candle Method.

Carbon Dioxide (ppm.) - This procedure and all chemical reagents used in this analysis are from the Hach Chemical Company. All water samples are collected in 300 ml. Citrate Magnesium Bottles.

pH - Determinations are based on a portable pH Taylor Slide Comparator. This set has a range from 3.8 to 11.6 in .2 gradations.

Temperature ($^{\circ}\text{F.}$): Water temperatures, under the supervision of John McClain, Phase I, Fish Study, were being recorded by eight Ryan Thermorecorders with a range of 30° to 90° F. and a recording time of 45 days in selected areas throughout the year.

Seven recorders were housed in a protective pipe assembly designed by Ronald White. Each consisted of a 10 to 20 foot length of four-inch aluminum irrigation pipe with a locking cover. The cover was made by welding an aluminum disc to a flanged ring. The cover is placed on top of the coupling end of the pipe and a collar placed around the assembly so as to seal together the flanges of the cover

and the coupling. The instrument is suspended in the pipe from a nylon line attached to a welded loop on the underside of the cover and is prevented from falling through the pipe by a brass bolt across the bottom. A piece of chain is passed around a piling and secured by the same lock which secures the collar, providing a tamper-proof, non-removable installation. These assemblies were strapped to pilings with automotive hose clamps.

The eighth instrument was contained in a one-foot section of four inch galvanized pipe. A bolt runs through each end of the pipe and the recorder is hung on one of the ends. A twenty foot length of chain connects the pipe to a large concrete block placed on the bottom by the New Jersey Bureau of Navigation. The pipe is dropped overboard in a predetermined direction from the block to facilitate recovery with a grapple.

Three thermorecorders were placed in the Mullica-Great Bay Estuary (primary); three were placed in the Manasquan River (secondary); and two were placed in the Maurice River (secondary) (see Figures 4, 2 and 3 of Fish Study Section for exact locations). It will be noted that the thermographs placed in the secondary estuaries were to be used as a comparison to the primary estuary along with any fish data collected in the Fish Study. The physical-chemical survey did no sampling in the secondary estuaries.

All field water temperatures were recorded with a Tele-Thermometer indicator with a 50 foot probe. This instrument has been tested and found to have a $\pm .3$ deviation. All air, and occasionally surface, temperatures were recorded by Taylor pocket thermometers in 2° Fahrenheit (F) gradations, range -30° to 120° F., with a $\pm .5$ deviation.

Bottom water sampling: All sub-surface water samples were taken with a one-liter water sampler attached to 50 feet of line, calibrated every two feet. If strong currents are encountered, four or five pound window sash weights are attached to the end of the water sampler.

Nutrient Analyses: Procedures and all chemical reagents used for these analyses were taken with the portable colorimetric field kits supplied from the Hach Chemical Company.

Total Phosphate Test Kit (ppm). Model PO-21

Nitrate-Nitrite Test Kit (ppm). Model NI-10

Ammonium Nitrogen Tester (ppm). Model NI-8

Detergents Kit (ppm). Model DE-2

Tidal data was obtained from the Coast and Geodetic Survey Tide Tables, Atlantic Coast of North America. Water temperatures for the Atlantic Ocean off Atlantic City were obtained from the Coast and Geodetic Survey. Eight Model D Waterproof Ryan Thermographs were used to record year round temperature data. Coast and Geodetic Survey Charts with a scale of 1:24000 were used for all morphometric measurements. Linear measurements were obtained with the use of a map rotometer. All area measurements were computed with a Compensating Polar Planimeter.

Phase II, Physical-Chemical Studies, has been divided into five major categories:

I. Water Quality. From November 1968 through May 1970, with the exception of September 1969 to write Annual Report, bi-monthly collections of surface and bottom waters were made at fourteen stations. Six of these stations corresponded to the plankton stations discussed in the Fish Study. Analyses of water samples

usually were completed within five hours after collections.

The following is a list of the stations sampled (Figure 4):

<u>Bay Stations</u>	<u>River Stations</u>
B-1 Coast Guard Station (Little Egg Inlet)	R-0 Deep Point (mouth of Mullica River)
B-2 Cape Horn	R-3 Akimbo Point
B-3 Light #20	R-6 French Point
B-4 Mid-Bay	R-9 Collins Point
B-5 Graveling Point	R-12 Hog Island
	R-14 Lower Bank
	R-17 Green Bank

Main Tributaries

B-0 Bass River (mouth)
W-0 Wading River (mouth)

When weather conditions did not permit sampling by boat, then water samples were collected by car from the following shore stations:

<u>Bay Stations</u>	<u>River Stations</u>
SB-1 Coast Guard Station	SR-6 Chestnut Neck Dock
SB-5 Graveling Point	SR-12 Clarks Landing
	SR-14 Lower Bank Bridge
	SR-17 Green Bank Bridge

Main Tributaries

SB-0 Bass River Oyster House Dock

II. Transects. This type of sampling was conducted by boat, consisting of a continuous zig-zag pattern initiated at Little Egg Inlet following the Intercoastal Waterway Channel and continuing by compass throughout the bay and ending at Oysterbed Point Light, near the mouth of the Mullica River (Figure 5). Surface temperature readings and salinity samples were collected two or more times a month when possible from each transect on both tidal cycles.

Surface temperatures were being recorded from the Tele-Thermometer indicator with a 50-foot probe. The probe was attached to the transom of the boat about six inches below the water line. Salinity samples were collected in 8 oz. prescription bottles and

were brought back to the laboratory for analysis done with the wide range Salinity Hydrometer.

The locations of sampling on each transect were determined by distance versus time method. Results will provide a monthly mean distribution pattern for surface salinities and temperatures on both tidal cycles.

III. Land Usage. This particular survey was conducted by car either visiting each of the Soils Conservation Offices in the various counties or by road survey. It was initiated with the aim of getting some idea of how lands adjacent to this estuary were being used. It could indicate sources of pollution and/or potential sources of pollution.

IV. Nutrient Water Quality. During October 1969 through May 1970 surface water samples were collected monthly at six stations on a falling tide. During the winter months, two stations could not be sampled (NB-3 and NR-0).

The following is a list of the stations that were selected and sampled (see Figure 4):

<u>Bay Stations</u>	<u>River Stations</u>
NB-1 Coast Guard Station (Little Egg Inlet)	NR-0 Near Bassetts Bay
NB-2 Near mouth of Big Creek	NR-7 Garden State Parkway Bridge
NB-3 Light #20	NR-14 Lower Bank Bridge

The following tests were run on water samples collected:

- A. Nitrogen Cycle
 - (1) Ammonium, Nitrogen (NH_4)
 - (2) Nitrite (NO_2)
 - (3) Nitrate (NO_3)
- B. Phosphate Cycle
 - (1) Orthophosphate
 - (2) Metaphosphate (poly -)
 - (3) Organically Bound Phosphate
- C. Detergents

Surface temperatures, salinities and pH were also taken along with these tests.

V. Pesticides. Analyses were originally planned to be run on mud, selected fish and/or invertebrates. Spearing was selected as a pesticide indicator because of its variability of tolerance and the quantity found during any period of the year. Anchovies and white perch were used when spearing were not available.

Fish were collected monthly from both bay and river seining stations by estuarine personnel and kept frozen in sterile plastic bags until time of analysis.

FINDINGS

Water Quality. All water quality data collected during this type of sampling from November 1968 through March 1970 are listed in Tables 1 to 14. All data ranges for the following stations being discussed will be considered surface water quality. Sampling was either stopped or conducted at shore stations due to weather or ice conditions in the winter months.

Coast Guard Station (Little Egg Inlet): Station B-1 lies approximately 430 yards off the Coast Guard Station in the Intra-coastal Waterway at Buoy C"3. Adjacent to Buoy C"3 lies a sandbar, separating two channels, which at mean low water has a depth range of one to four feet. The Intracoastal Waterway channel, where B-1 is located, has a depth at mean low water of 40 feet. Bottom is hard sand; subject to very strong currents.

Surface water temperatures at this station ranged from 28° to 79° and air temperatures from 27° to 87° F. (Table 1). Salinity varied from 18.9 ‰ to 31.6 ‰. pH readings were found to be

basic (7.9 to 8.5). Dissolved oxygen concentrations ranged from 2.9 to 12.2 ppm (see also \circ/\circ saturation Figure 6). Carbon dioxide values were from 3.5 to 12.1 ppm. Turbidity readings were found to range from clear to 75 JTU (Jackson Turbidity Units).

Cape Horn, Great Bay: Site B-2, located on the northeast side of Great Bay, was sampled approximately 700 yards from shore. Depth at mean low water in sampling area is four feet. Bottom is composed of sticky mud and shellfish beds.

Surface water temperatures range from 35.5° to 78° F. and air temperatures from 23.6° to 78° F. (Table 2). Salinity varied from 21.4 \circ/\circ to 30.7 \circ/\circ . pH readings were the same as the Inlet (7.9 to 8.5). Dissolved oxygen concentrations ranged from 5.1 to 11.5 ppm., and carbon dioxide from 4.7 to 12.6 ppm (see also Figure 6). Turbidity values were found to range from clear to 30 JTU.

Light #20, Great Bay: Station B-3, is located on the Intracoastal Waterway on the southern portion of Great Bay, about 1200 yards from shore. At mean low water it is seven feet in depth. Bottom is composed of sticky mud. During an ebbing tide, Little Bay which lies adjacent to this bay partially empties into it.

Surface water temperatures ranged from 38° to 80.5° F. and air temperatures from 38° to 85° F. (Table 3). Salinity varied from 14.8 \circ/\circ to 29.5 \circ/\circ . All pH readings were basic (7.9 to 8.3). Dissolved oxygen values recorded ranged from 5.7 to 11.2 ppm. and carbon dioxide from 3.9 to 12.7 ppm. (see also Figure 6). Turbidity readings did not exceed the minimum sale of 24 JTU.

Mid-Bay, Great Bay: Area B-3 is roughly 2500 yards from Graveling Point, south, at the intersection of bearings 105° E. to Seven Islands and 346° NNW to Graveling Point. At mean low water

depth is seven feet and bottom is composed of sticky mud.

Surface water temperatures range from 35° to 82.5° F. and air temperatures from 38° to 83° F. (Table 4). Salinity varied from 15.7 ‰ to 28.7 ‰. All pH readings were basic (7.9 to 8.4). Dissolved oxygen concentrations ranged from 5.4 to 12.0 ppm, and carbon dioxide readings ranged from 2.3 to 10.8 ppm. Turbidity readings recorded from clear to 30 JTU.

Graveling Point, Great Bay: Station B-5 is located 680 yards off Graveling Point on the northern portion of the bay. This area is located near shellfish beds and has a depth at mean low water of seven feet. Bottom is composed of sticky mud.

During the winter months, sampling was conducted from a shore station (Figure 4). Surface water temperatures range from 28° to 82° F. and air temperatures from 22° to 86° F. (Table 5). Salinity varied from 16.9 ‰ to 26.8 ‰. pH values recorded were basic (7.5 to 8.3). Dissolved oxygen concentrations ranged from 5.5 to 12.3 ppm, and carbon dioxide from 2.8 to 11.7 ppm. (see also Figure 6). Turbidity readings recorded from clear to 160 JTU.

Deep Point, Mullica: This station has been designated as the mouth of the Mullica River (R-0) and has a depth range at mean low water to be from 17 to 30 feet. Bottom is composed of mud.

Surface water temperatures ranged from 31.8° to 83.5° F. and air temperatures ranged from 39° to 82° F. (Table 6). Salinity varied from 10.0 ‰ to 24.6 ‰. Some pH readings recorded were found to be slightly basic (7.3 to 8.3). Dissolved oxygen concentrations ranged from 4.3 to 11.8 ppm, and carbon dioxide from 4.4 to 10.1 ppm. (see also Figure 6). Turbidity values recorded from clear to 70 JTU.

Akimbo Point, Mullica: Site R-3 (river mile 3) has a depth range at mean low water of 13 to 19 feet. Bottom was found to be composed of mud.

Surface water temperatures ranged from 31.8° to 82° F. and air temperatures from 39° to 91° F. (Table 7). Salinity varied from 8.7 ‰ to 23.1 ‰. pH readings were found to be near neutral or slightly basic (6.9 to 7.9). Dissolved oxygen concentrations ranged from 4.0 to 12.0 ppm. and carbon dioxide from 2.4 to 12.3 ppm. (see also Figure 6.) Turbidity values were low ranging from clear to 35 JTU.

Bass River (Main Tributary): Station B-0 was located approximately 200 yards from its mouth during most of the year. During this time all data were collected up river (1100 yards) at the Oyster House Dock (Figure 4).

Surface water temperatures were found to range from 30.5° to 82° F. and air temperatures from 21° to 91° F. (Table 8). Salinity varied from 2.8 ‰ to 19.7 ‰. pH readings ranged from slightly less than neutral to slightly basic (6.7 to 7.7). Dissolved oxygen concentrations recorded ranged from 3.8 to 12.0 ppm. and carbon dioxide from 3.1 to 14.2 ppm. (see also Figure 6). Turbidity recorded ranged from clear to 110 JTU.

French Point, Mullica: Site R-6, near shellfish beds, at mean low water has a depth of 13 feet and a bottom composition of hard sand. Whenever weather conditions prevented sampling by boat, data was recorded off Chestnut Neck Dock (650 yards from original station, Figure 4).

Surface water temperatures ranged from 29° to 82° F. and air temperatures from 21° to 94° F. (Table 9). Salinity varied from

2.8 ‰ to 20.7 ‰. pH values ranged from slightly acid to slightly basic (6.7 to 7.7). Dissolved oxygen concentrations ranged from 3.4 to 12.6 ppm. and carbon dioxide from 2.5 to 15.8 ppm. (see also Figure 6). Turbidity readings recorded from clear to 250 JTU.

Wading River (Main Tributary): Site W-0 was sampled 200 yards from its mouth during most of the year. Depth at mean low water is nine feet and a bottom composed of mud.

Surface water temperatures range from 36° to 83° F. and air temperatures from 39° to 93° F. (Table 10). Salinity varied from 1.0 ‰ to 16.7 ‰. pH values ranged from acid to slightly basic (5.7 to 7.5). Dissolved oxygen concentrations ranged from 3.6 to 11.9 ppm. and carbon dioxide from 2.6 to 14.6 ppm. (see also Figure 6). Turbidity values recorded from clear to 55 JTU.

Collins Point, Mullica: Site R-9 lies adjacent to Swan Bay and is 1100 yards from the mouth of the Wading River going up stream. At mean low water, the channel has a depth range of seven to 16 feet. Bottom consists of hard sand.

Surface water temperatures range from 36° to 83° F. and air temperatures from 39° to 89° F. (Table 11). Salinity varied from 1.0 ‰ to 14.8 ‰. pH values ranged from acid to slightly basic (5.7 to 7.5). Dissolved oxygen concentrations ranged from 3.6 to 11.9 ppm. and carbon dioxide from 3.0 to 14.6 ppm. (see also Figure 6). Turbidity readings recorded from clear to 45 JTU.

Hog Island, Mullica: Site R-12 at mean low water has a channel depth of eight feet. Bottom is made up of mud with some vegetation. Sampling was not attempted here during December, January and February but rather at Clarks Landing 1000 yards up

river (Figure 4). Here the bottom is composed of sticky mud and probably was the cause for a great deal of the turbidity recorded here.

Surface water temperatures ranged from 30° to 84° F. and air temperatures from 31° to 92° F. (Table 12). Salinity varied from .3 ‰ to 11.8 ‰. pH values recorded ranged from acid to slightly basic (4.3 to 7.3). Dissolved oxygen concentrations ranged from 3.3 to 12.0 ppm. and carbon dioxide from 2.4 to 15.6 ppm. (see also Figure 6). Turbidity readings ranged from clear to 290 JTU.

Lower Bank Bridge, Mullica: Site R-14 is approximately 100 yards from bridge going upstream and is adjacent to the Pace Maker Boat Works. At mean low water the channel has a depth of seven feet. Bottom consists of mud with sand along shore. Some vegetation is prominent. During the winter months sampling was conducted off the bridge.

Surface water temperatures range from 31° to 84° F. and air temperatures from 19° to 93° F (Table 13). Salinity varied from $<.1$ ‰ to 5.2 ‰. All pH readings were acid (4.1 to 6.9). Dissolved oxygen concentrations ranged from 3.6 to 13.0 ppm. and carbon dioxide from 2.8 to 17.3 ppm. (see also Figure 6). Turbidity values were low ranging from clear to 40 JTU.

Green Bank Bridge, Mullica: Site R-17 is located approximately 100 yards from bridge. At mean low water it has a channel depth of eight feet. The bottom is composed of mud and the shore consists of hard sand with gravel. This station is considered fresh water and vegetation is present.

Surface water temperatures ranged from 30.5° to 83.5° F. and air temperature from 19° to 95.5° F. (Table 14). Salinity varied from $<.1$ ‰ to 1.7 ‰. All pH readings were acid (4.1

to 5.9). Dissolved oxygen concentrations ranged from 4.1 to 12.4 ppm. and carbon dioxide varied from 2.9 to 18.2 ppm. (see Figure 6). Turbidity readings recorded ranged from clear to 40 JTU.

On August 21, 1969 a 12-hour temperature and salinity analysis was conducted in Little Egg Inlet approximately 300 yards off Seven Bridges Road (near Coast Guard Station) within the Intra-coastal Waterway. This station was sampled hourly at three different levels, namely surface, middle and bottom. Table 15 lists the data recorded from the Inlet and Figures 7 and 8 represent top and bottom temperatures and salinity patterns.

As previously mentioned in Methods and Procedures section, three thermorecorders were installed in the Mullica-Great Bay Estuary. The location of each instrument was as follows: (1) attached to the dock pilings of Seven Islands (Fish Factory); (2) on the bottom near Oysterbed Point; and (3) attached to the pilings off the Lower Bank Bridge (Figure 4). All three recorders were installed during June 1969 and ran periodically through May 1970. During this period, data was lost for 111 days at the fish factory, 114 days at Oysterbed Point and 96 days at Lower Bank Bridge. In summary, the malfunctions were attributed to winter conditions and not being able to recover the instruments or to the recorder itself.

In the secondary estuaries, three recorders were placed in the Manasquan River and two in the Maurice River during January 1970 through May 1970. The locations in the Manasquan River were as follows: (1) Bay Head-Manasquan Canal attached to Route #88 bridge; (2) Route #70 bridge, and (3) at the Coast Guard Station in Manasquan Inlet (Figure). During this period, data was lost for 11 days at the Coast Guard Station, 45 days at Route #70 bridge and 38

days at Route #88 bridge.

The two instruments located on the Maurice River were as follows: (1) station M-1 at Hayes Marina, and (2) station M-2 at Burchans (Figure). During time of recording, station M-1 thermometer malfunctioned for 60 days and station M-2 malfunctioned for 15 days.

Figures 9, 10, 11, 12, 13, 14, 15 and 16 represent a graphic summary of the data recorded from the thermographs installed at the locations just mentioned.

Collins Cove: During the first part of January 1969, attention was focused to an area on the Mullica River called Collins Cove. This area consisted of a 36-foot deep dredge hole created when the Garden State Parkway was being built. Its location is approximately a quarter of a mile away from the Mullica River Parkway Bridge going up river; entrance is gained through Port Republic Hunting Grounds off Clarks Landing Road.

For the past three years, ice fishing in this area has proved to be very productive for white perch. A hydrographic study was undertaken to determine what conditions caused the white perch to be so abundant in this area (Tables 16 and 17). From the Use Survey, it was learned that fish were being caught between 12 to 15 feet below surface. Sampling from the ice and later on by boat revealed that during the first part of January 1969 surface temperatures varied from 30.2° to 31.8° F., whereas at 15 feet temperatures ranged from 31.5° to 35° F. and bottom from 46.5° to 48° F. There was a temperature difference ranging from top to bottom of 16.2° to 16.5° F. (Table 16). The second portion of January surface temperatures ranged from 29.5° to 35.5° F.; at 15 feet temperatures recorded from

30° to 34°F. and bottom 39° to 49° F. The recording of 39° F. was the last reading taken for this month at the bottom. It was during this time that a cooling period became evident until finally in March the surface temperatures were warmer than bottom.

Salinity readings also sharply increased from surface to bottom. Maximum bottom salinity recorded was 25.9 ‰; other readings were close to 24 ‰. Readings of this magnitude are typical of the bay. Dissolved oxygen concentrations sharply decreased from surface to bottom (it was not until the end of January 1969 that traces of oxygen were recorded on the bottom). As the temperature and salinity would increase, dissolved oxygen would decrease. A vertical comparison of Collins Cove to conditions that existed during January 1969 in the Mullica River can be seen in Table 16-A.

Readings taken in January 1970 are compared with January 1969 in Figure 17. Maximum bottom water temperatures recorded were only 37° F., a 12° F. difference from 1969's highest reading. Salinities were found to be less than 20 ‰; however, readings of this nature still were atypical for the area. Dissolved oxygen values were found still to have a wide difference from top to bottom; however, oxygen was recorded present on the bottom in all analyses as compared to 1969 sampling. February 1970 revealed a cooling period had taken place as in the previous year.

Secondary Water Quality Stations. Water quality was conducted at four other location areas for a brief period during the sampling year because of their possible effects on the estuary. They were the following: two main tributaries -- Bass and Wading Rivers; Upper Watershed Region (from R-14 going up river as far as Route #542); and the Intracoastal Waterway (Main Marsh Thorofare) around Little

Bay, adjacent to Great Bay (Figure 4).

During the months of July and August 1969 water analyses were taken once from each of the main tributaries (Tables 18 to 21).

In February 1970 sampling was done from shore stations along the Upper Watershed Region terminating at Route #542 (Batsto Road) which runs perpendicular to both Mullica and Batsto Rivers. Nutrient samplings were also included in this particular analysis (Table 22).

Little Bay and the Intracoastal Waterway that lies around it was sampled during the month of August 1969 (Table 23).

Transects. Plates 1 to 4 are highs and possible lows from six months of monthly mean surface isohalines and isotherms recorded in Great Bay Estuary during 1969-1970. Problems arose that would not allow a completion of this portion of the report for the plotting of minimum isohalines and isotherms patterns.

Nutrient Water Quality. From October 1969 through May 1970 surface temperatures, salinities, and pH were taken along with the nutrient study (Tables 24 to 30). Due to chloride interference, ammonia determinations were limited to the river stations. Data results from the nitrogen tests were found reasonable; however, there is the possibility that chloride may also interfere with this analysis. A change in technique may be considered for next year's study.

No appreciable traces of nitrites were found at any of the selected stations throughout the sampling year.

Coast Guard Station, Little Egg Inlet: Site NB-1 is located in the same area as the hydro-station described previously. Sampling was also conducted from Seven Bridge Road shore when weather conditions prevented the use of a boat.

Surface water temperatures ranged from 29° to 65.9° F. and air temperatures from 20° to 68° F. (Table 24). Salinity varied from $20.5^{\circ}/\text{oo}$ to $32.5^{\circ}/\text{oo}$. All pH readings were basic (7.9 to 8.1). Nitrate readings were few ranging from 0.0 to .18 ppm. Orthophosphate values ranged from .02 to .76 ppm.

Big Creek, Great Bay: Site NB-2, located on the northern portion of the bay, was sampled approximately 100 yards from the mouth of Big Creek (Fl. #2 light) in the bay. During the months of December, January and February, samples were taken from the shore of Graveling Point (approximately 2700 yards from outlet of Big Creek).

Surface water temperatures ranged from 31° to 64.4° F. and air temperatures from 30° to 67° F. (Table 25). Salinity varied from $17.1^{\circ}/\text{oo}$ to $31.2^{\circ}/\text{oo}$. All pH were basic (7.7 to 8.0). Nitrate readings ranged from 0.0 to .13 ppm. and orthophosphate from .12 to .92 ppm.

Light #20, Great Bay: Site NB-3 is located in the same area as the B-3 station.

Surface water temperatures ranged from 40° to 64.2° F. and air temperatures from 47° to 65° F. (Table 26). Salinity varied from $14.1^{\circ}/\text{oo}$ to $32^{\circ}/\text{oo}$. All pH readings were basic (7.7 to 8.0). Nitrate values were very few ranging from 0.0 to 0.09 ppm. Orthophosphate readings ranged from .06 to .76 ppm.

Basses Bay, Mullica: Site NR-0 is located 600 yards from Deep Point, downstream near Basses Bay.

Surface water temperatures ranged from 43° to 64.7° F. and air temperatures from 45° to 66° F. (Table 27). Salinity varied from $14.2^{\circ}/\text{oo}$ to $25.4^{\circ}/\text{oo}$. pH values varied from acid to slightly basic (5.5 to 7.7). Very few nitrate readings were recorded (0.0 to .18 ppm.). Orthophosphate readings ranged from 0.0 to .44 ppm.

Garden State Parkway Bridge, Mullica: Site NR-7 is located 100 yards from bridge upstream. During winter months samples were acquired from shore.

Surface water temperatures ranged from 30° to 66° F. and air temperatures from 31° to 68° F. (Table 28). Salinity varied from 5.0 ‰ to 21.8 ‰. pH readings ranged from acidic to slightly basic (5.4 to 7.3). Nitrate values ranged from 0.0 to .44 ppm. Orthophosphate readings were low ranging 0.0 to .40 ppm. except for two instances where high readings of 2.0 and 5.6 ppm. were found. Ammonia readings were high ranging from .6 to 3.5 ppm.

Lower Bank Bridge, Mullica: Site NR-14 is located in the same area as the R-14 station described previously.

Surface water temperatures ranged from 30° to 67° F. and air temperatures from 32° to 78° F. (Table 29). This station is considered basically fresh water. During this particular sampling, salinity ranged from 0.0 ‰ to .2 ‰ with the exception of one high reading of 6.5 ‰. All pH readings were acidic (4.4 to 4.9). Nitrate values varied from 0.0 to 1.23 ppm. Orthophosphate readings ranged from 0.0 to 2.4 ppm. and ammonia readings were low ranging from .5 to 1.4 ppm. except for one high reading of 4.4 ppm.

DISCUSSION

Surface water temperatures during the winter months of December 1968 through the first part of February 1969 ranged from 29° F. to 32.5° F. The temperature distribution throughout the estuary had not differed more than 2.5° F. at any one hydro-station. This would seem to indicate a uniform temperature existing throughout

the estuary during this period. However, if one would note the mean surface temperatures for each of these months in both river and bay, February 1969 would show a rise in temperature close to 35° F. instead of the uniformity just mentioned (Figure 18.). This sudden rise in temperature is due to the changes that took place in the later days of February. However, December 1969 through the first part of February 1970, surface water temperatures ranged from 28° to 46.4° F. During the month of December 1969 water temperatures were found still warm ranging from 36.3° to 46.4° F. as compared to last year's recordings. From January 1970 to early February surface water temperatures ranging 28° to 34° F. were comparable to last year's winter months. The temperature distribution throughout the estuary during that period had not differed more than 5° F. at any one station. From Tables 1 to 14 one can note a definite air-temperature relationship. During November 1968 through March 1970 the temperature difference between surface and bottom ranged 0.0° to 6.5° F.

From the hydro data mean surface temperatures for both river and bay stations were plotted and compared with ocean temperatures recorded at the Steel Pier in Atlantic City by the U. S. Coast and Geodetic Survey (Figure 18). It would seem that the bay was colder than both the river and the ocean from December 1968 until March 1969. During March there was a change over leaving the ocean colder until about the middle of August 1969. September shows the bay cooling off and becoming colder at the end of October 1969.

Figures 9 to 16 are monthly means and extremes of thermorecorders in the Great Bay Estuary. It was during December 1969 the lowest extreme was recorded at the fish factory on Seven Islands (28.8° F). This cold front was recorded at Oysterbed Point in January

1970 (34.9°F.) and at the Lower Bank bridge in February (30°F.). The warmest extreme at all three locations was recorded in July 1969 as being 87.3°F. at the fish factory; Oysterbed Point was 81.5°F. and 84.5°F. at R-14.

At Route 88 Canal bridge in the Manasquan River, the lowest extreme was recorded in January and February 1970 (28°F.), whereas Route 70 Bridge was only 31°F. in January, and at Manasquan Coast Guard Station 32°F. also in January and February. Recorders were not in long enough to determine the warmest extreme.

In the Maurice River, station M-1's lowest extreme was recorded in January and February 1970 (32°F.) and station M-2 recorded also in January and February 1970 (29°F.). Recorders were also not in long enough to determine the warmest extreme.

Surface dissolved oxygen ranged from 2.9 to 12.6 ppm. During the first part of August 1969 heavy rains for a few days caused the low readings. Except for August, dissolved oxygen values did not drop below 5.0 ppm. or 63 % saturation. Oxygens ranged from 9.7 to 12.6 ppm. during the colder months but gradually decreased with an increase in temperature. Surface and bottom dissolved oxygen differed by 0.0 to 2.5 ppm.

All surface pH readings for the bay and Little Egg Inlet ranged from 7.5 to 8.5, and the river stations from 4.1 to 8.4. The difference from surface and bottom deviated 0 to .8.

Salinity for the bay ranged from 14.8 ‰ to 31.6 ‰ and the river from $<.1$ to 24.6 ‰ . The maximum reading of 31.6 ‰ was observed at the surface of station B-1 while a minimum of less than $.1\text{ ‰}$ was recorded at stations R-17 and R-14 Tables 1, 13 and 14). Their respective ranges were $<.1\text{ ‰}$ to 1.7 ‰ and $<.1\text{ ‰}$

to 6.2 ‰. At R-17 station only twice has there been readings exceeding 1 ‰, attributable to storm tides or moon tidal cycles.

Free carbon dioxide analysis was initiated during March 1969. Water analyses in the bay revealed a surface range from 2.3 to 12.7 ppm. and in the river from 2.4 to 18.2 ppm. Figure 19 shows upstream sampling with the most degree of variability and the bay the least. It is generally recommended that the free carbon dioxide should not exceed 25 mg/l for aquatic animals. Carbon dioxide values were found to be higher during the summer months with the month of August having the highest values, probably due to the heavy rainfall in this area. During the winter months, the bay values were higher than the river.

Turbidity values ranged from clear to 290 JTU (Jackson Turbidity Units). It will be noted that the word "clear" does not indicate lack of turbidity but that it will fall in the range of 5 to 24 JTU. There was not definite distinction made at this time for this particular range other than by estimated approximations. The Jackson Turbidimeter has a usable range only above 25 JTU; lower turbidities cannot be measured on this instrument. Turbidity readings were less in the bay as compared to the river stations. Readings were taken mostly during the winter months. Most of the turbidity values recorded in the late 1969 and early 1970 were taken at shore stations -- off beaches, docks or bridges during ice conditions.

Nutrient Analysis. As stated in the section Findings, there were no indications of detergents or nitrite being present.

Nitrate. Nitrate values in the bay were found to be low and only present during the winter months. In the river readings were also recorded during the winter months along with an upstream

rise in values from the mouth of the river. Station NR-14, the farthest upstream station, had a maximum of 1.23 ppm recorded during the month of January. A secondary water quality sampling of the Upper Watershed was initiated during February 1970 at NR-14 and proceeded upstream to where Rt. #542 (Batsto Road) crosses over the Mullica and Batsto Rivers (Table 22). Nitrate values were found to be 1.50 and 1.41 respectively.

Ammonia. Ammonia water samples collected in the river ranged from .5 to 3.6 ppm. An exception was station NR-14 with 4.4 ppm, found in March 1970 contrasting from its range of .5 to 1.4 ppm. Ellis (1937) notes that although the tolerance of fish differs with species and other factors, 2.5 mg./l of ammonia is considered harmful to fish in the 7.4 to 8.5 pH range.

The Mullica River was highest in ammonia during the months of October through December and began decreasing to a low in February. From here there is an upswing and one can only assume it will reach its peak during the summer.

Phosphate. Orthophosphate, the soluble form of phosphate, was found in the bay ranging from .02 to .92 ppm. The highest values were recorded during November, January and April. The river readings ranged from 0.0 to 5.6 ppm. and were highest during the months of December and January and lowest during March.

From the February sampling upstream, it was learned that 2.8 ppm. of PO_3 was recorded at Sweetwater and 2.0 ppm. on the upper Mullica River Branch.

Figure 20 shows monthly mean values plotted to compare NO_3 and PO_3 values during the eight months surveyed.

Pesticide Analysis: All samples were analyzed by Quality Control Lab in Philadelphia for chlorinated hydrocarbons. Results were given in ppm. total DDT by gas chromatography.

Table 30 shows that B HC (alpha, beta, gamma and delta) and Hepta Epoxide were $\leq .01$ ppm. Dieldrin was present in only one out of eight samples, the rest were $\leq .01$ ppm. DDD and DDE were present in all samples along with DDT-p,p'. DDT-o,p' was present in only one sample, the rest recording $\leq .01$ ppm.

Total DDT recorded in the bay ranged from .28 to .56 ppm. and the river from .56 to 1.12 ppm. It would seem that from the data pesticide levels are higher in the fall.

Land Usage. Killam (1969) reports that the total area in the Mullica River watershed includes approximately 328 square miles in Burlington County, in addition to 31 square miles in Ocean County, 154 square miles in Atlantic County and 65 square miles in Camden County. Approximately thirty to forty percent of the land area in the watershed has been purchased by the State of New Jersey and has been designated as the State Forest Park and Wharton Tract.

Soil Survey #5 (Mount Holly) reports that Burlington County is the largest county in the State of New Jersey, with a population of 224,499 in 1960, covering 827 square miles. It roughly covers an area of 529,351 acres, of which 524,160 are land and 5,191 acres are water. The county extends from the Delaware River to the Great Bay

on the Atlantic Ocean comprising about 54% forest, 30% farmland (184,727 acres), 12% urban and 4% federally-owned land.

"Basically Burlington is devoted to farming where most of the productive farmland is in the 1/3 of the county paralleling the Delaware River and 2/3 portion to the east is mostly woodland (much of this section is in the 20% of the county that is state-owned Forests and Parks).

"From the geology and topography view, this county is alluvial sand, gravel, loam and clay mixed. Along the Delaware River extending back from 10 to 14 miles is rather fertile loam. To the east of this loam the soil is mostly sand over clay which extends to the marshes and bays of the ocean. There lies a narrow strip between the loam and sand districts (Pines) that produces oak. To the east of 'Pines' and extending well into Ocean County is a section of stunted growth called the 'Plains'. In the southern portion of this County, bordering on the Mullica River, are located two large iron ore deposits.

(1) lies along the Atsion River and its branches.

(2) the other along the Wading River and its many branches.

"All rivers within this County either flow southwest to the Atlantic or northwest to the Delaware River. Those emptying into the Ocean are Mullica, Wading, Batsto and Bass Rivers, and those into the Delaware are Crosswick, Black, Craft, Assicunk, Rancocas and Pennsauken Creek.

"The lands that the State of New Jersey owns is a total of 275,757 acres under the jurisdiction of Department of Conservation and Economic Development. Within Burlington County there is over 100,000 acres of this land (Table 31).

Within the Pine Region, the most important industry are cranberries and have been cultivated near Pemberton since about 1825, but production on a commercial scale did not begin in southern New Jersey until after the Civil War. However, due to insect, disease and drought disasters lead to the abandonment of cranberry acreage. Such lands became covered with red maple, sweet bay, southern white cedar and various shrubs, grasses, and sedges. Several of these abandoned cranberry bogs recently have been cleared and flooded to provide shallow lakes around which developers have constructed numerous small houses (Presidential Lakes, Lebanon Lakes, Shamong Estates, etc.).

"The characteristic lowlands are associated to the blueberry and cranberry crops extensively produced in this County. A great deal of these crops are produced south and southwest of Chatsworth. Other private holdings are located on Bass River, Shamong, Tabernacle, Washington and Woodland Townships. Both crops require a good water supply for efficient production. Blueberries need ground water held constant in summer while cranberries need water in fall for harvesting and in winter and spring for frost production. Land currently developed for cranberry and blueberry production are generally graded or smoothed to insure surface drainage. This involves stockpiling of the surface soil, smoothing and grading the subsoil to a designed grade and replacing the surface soil. Ditches are dug for drainage and canals are constructed to carry water where it is needed. Excess excavated material is spread over the low areas."

The towns that are found in the immediate area sampled in the Great Bay Estuary are very small and are situated along the Burlington-Ocean County border. They are as follows: New Gretna

(largest of this area), Wading River (few homes scattered along Turtle Creek Road which runs parallel with the Wading River), Lower Bank comprises mostly homes and Pacemaker Boat Works which is located on the Mullica River adjacent to the Lower Bank Bridge; Green Bank, located on Route 563, homes are located parallel to the Mullica River; Crowleystown, located on Route #542; Batsto, historic site located on Batsto-Washington Road.

Killiam (1969) reports that at the present time there is only one treatment facility located within the Mullica Watershed of Burlington County. This plant is located in Washington Township and is owned and operated by the Pacemaker Corporation (Figure 3). The plant has a design capacity of 0.01 MGD and discharges the treated effluent into the Mullica.

"The only other inhabited sites are small recent developments: Shamong Park Estates and Woodland Lakes. These are located on the north-most section of the Wading River. They include approximately 50 dwellings."

Special Report #29 (Toms River) states that Ocean County lies within the Coastal Plains in east central New Jersey between latitude $39^{\circ} 30'$ and $40^{\circ} 10'$ North and between longitude $74^{\circ} 02'$ and $74^{\circ} 33'$ West. The Atlantic Ocean forms the eastern boundary of the county. It comprises a total area of 750 square miles, of which 639 square miles is land. Barnegat Bay along the eastern margin of the county comprises most of the water area. Upland area consists of 563 square miles (excluding salt marsh and beach area), of which approximately 87% was forested with stands of pine, oak and cedar in 1939 (Moore, 1939).

"In land utilization, agriculture is a minor factor. In 1959, 7% of land was devoted to agriculture. The poultry industry

accounted for 11 million of the 12 million dollars in farm products sold in 1959. Also blueberries and cranberries are a main specialty crop. More than 3/4 of the land area of this County lies below an altitude of 150 feet and much of this is occupied by swamps, streams and salt marsh.

"The County is drained principally by east and southeast flowing consequent streams of the Coastal drainage area. These streams have a dendritic drainage pattern from north to south. The most important streams are the Manasquan River, Metedeconk River, Toms River, Cedar Creek, Forked River, Oyster Creek and Mill Creek. Other streams such as Crosswick Creek flows northward to the Delaware River. The coastal streams drain into Barnegat Bay, Little Egg, and Great Bay."

An area that over the years has given way to home waterfront developments lies between State Route 9 and Great Bay Boulevard intersecting in Tuckerton. There are two prominent developments that have risen from the salt marshes on the northern portion of Great Bay namely Atlantis Development and Mystic Island. Mystic Island is the larger of the two developments with constant dredging and filling still taking place. The principal outlet for boats from this area is by Big Creek emptying into Great Bay. Unfortunately, time did not allow statistical data to be presented concerning this area.

Census Facts (Days Landing) reports that Atlantic County contains approximately 368,000 acres of land area running from the Delaware River along the channel of the Mullica River to Little Egg Inlet of the Atlantic Ocean. Of the total just mentioned, 43,688 acres or 12% are classified as farm land. Since 1910, farming has been a declining trend.

Towns having an immediate effect on the Great Bay Estuary within Atlantic County are Sweetwater, Pleasant Mills and Hammonton. It can also be noted that the Hammonton Sewage Plant has its drainage system located on the Mullica River Watershed. There are a few scattered homes found along Clarks Landing Road (runs parallel with the Mullica River) and others with waterfront docks located up around Sweetwater.

State-owned land in this county comprises Port Republic Hunting and Fishing Grounds, and a portion of the Green Bank State Forest. Brigantine National Wildlife Refuge, located in both Atlantic and Ocean Counties, is federally owned.

In all three counties there are camping grounds located in the various State Forests and Parks. It was mentioned before that there are cranberry bogs located throughout the three counties from which their drainage empties into this Watershed.

Phase III. Use Studies
Paul E. Hamer

INTRODUCTION

Our survey of the use made of the Mullica River-Great Bay System was limited to the tidal waters and their adjoining marshland by practical limitations. A survey of the entire watershed was impossible since the cost of manpower would be prohibitive. Covering less than the entire watershed introduces problems of defining boundaries. The upland edge of the marsh is a clear-cut natural boundary, and the entire area within this boundary is open, making it easily observable from an aircraft. It is also the area that is most closely related to, and which has the greatest immediate effect upon, the estuarine resources. This study constitutes the most comprehensive one that has been focused on New Jersey's estuarine areas. A previous study (Younger and Hamer, 1954; Younger and Zamos, 1955) covered the marine sport fishery of the State in general but was not designed to reveal the extent of sport fishing in individual estuaries. Other studies, conducted in New Jersey, have concentrated on a particular sport or species. In the study herein described, we have endeavored to study all of the important recreational and vocational activities conducted within the study area throughout the year.

ACKNOWLEDGEMENTS

A number of individuals have been involved in this program. The study was begun by Charles Ritson, who was inducted into the Armed Forces shortly after the project began. Rodgers L. Todd conducted the work until his transfer from our Bureau. The survey was finally completed by John McClain. Russell Tilton assisted with field sampling during the entire study. Final analysis of the data

was carried out by the writer, with the assistance of Ferdinand Metzger.

METHODS

The man-days of activity expended in the project area were estimated from flight counts, while the estimated harvest was based on creel and bag checks. Sampling times and places were randomly chosen.

For each week of the survey (with the exception of January and February), two week days and one weekend day or holiday were randomly chosen for aerial surveys. During January and February three days per month, one weekend and two week days, were scheduled. The starting time for each of these flight days was also randomly chosen between the hours of 10 A.M. and 3 P.M., since this was shown to be the greatest activity period of the day (Briggs 1965).

Flights followed a predetermined path unless it was necessary to deviate to get complete counts. This occurred when large numbers of boats could not be counted on one pass, or when closer observation of marsh areas was necessary to find waterfowl hunters. The flight pattern generally adhered to began at Brigantine Channel. From there the observer flew to the town of Oyster Creek, then across the southern part of Great Bay to the Little Egg Coast Guard Station. He then flew to Graveling Point and up the Mullica River to the town of Green Bank, across country to the town of Wading River and down the Wading River, over the Bass River, over to and along Great Bay Boulevard to the mouth of Little Egg Inlet, completing the circuit. See Figure 1.

Flight time was generally a little more than one hour. An altitude of 200 feet was found to be generally desirable, but

occasionally lower or higher altitudes were used, depending on visibility and the kind of activity that was being enumerated at the moment.

To facilitate counting, the study area was broken up into readily definable sectors. Counts were made for each activity in each sector and recorded on a field sheet. The data was summarized on a monthly basis for each activity in each sector, with weekdays and weekend or holidays kept separate. Means for weekdays and weekend-holidays were then multiplied by the number of such days in the month on which no flights were made. This figure was added to the actual flight totals to arrive at an estimate for the month. The estimate is considered to be a minimal one, representing only the number of man-days during the peak use period. There is no doubt that individuals entered and left the study area both before and after the peak use period, but we know of no practical way of estimating this minor fraction of the total use figure.

Creel and bag checks were scheduled on the same days as flight counts, and on two additional randomly chosen days per week. Of these five days, three (randomly chosen) were spent interviewing boat fishermen and two interviewing bank fishermen, except during the hunting season when the number was reduced to two and one, respectively, and the other two days were devoted to hunter interviews. Bank fishermen interviews were scheduled by selecting the starting point on the route, and the starting hour (between 8 A.M. and 5 P.M.) randomly. For each party the interviewer recorded: time of interview, number of anglers, number of hours fished, the number of fish of each species taken, and the angler's place of residence. Enough parties were interviewed "just as they were leaving" to provide a

substantial estimate of the average number of hours fished per angler-day.

Boat anglers were interviewed for the same information as bank fishermen either when returning to a randomly chosen access point, which provided complete trip data, or on the water. It is felt that the incomplete interviews were the best way to include anglers who did not use the public access points in our survey.

The mean number of anglers per boat, derived from creel census data, was used to convert the boat counts obtained in the aerial survey to man-days of activity.

Hunters were interviewed at randomly chosen access points at the end of their day, for the same basic information as the fishermen were.

Harvest estimates were obtained by multiplying the average catch (or kill) per man-hour by the average number of hours per trip, and this figure was then multiplied by the appropriate activity estimate obtained by the flight count.

The following definitions were used in the study:

Bank fisherman - any individual fishing without a boat.

Boat fisherman - any individual fishing from a boat of any size or description.

Boating - any boat, the occupants of which were not obviously engaged in, or about to engage in, fishing, shellfishing, water skiing or hunting.

Catch/effort - average number of fish caught per hour spent fishing; fish per man-hour.

Fish/angler - average number of fish caught per trip; fish per man-day.

Other (Use) - activity that was unknown or which did not fit in one of the categories listed. Includes, but is not limited to, sightseers, bird watchers and other naturalists, non-fishermen attached to parties of bank fishermen, etc.

Shellfishermen - any individual harvesting clams, oysters, scallops or mussels.

RESULTS

Use Estimates

A total of 115 flights was completed out of 138 which were scheduled. The remaining 23 flights were cancelled because of unfavorable weather conditions. No adjustments were attempted in compiling the data. It would be reasonable to conclude that if counts could have been made on these days, they would have had a tendency to be lower than average because of weather conditions. By eliminating these low counts, the estimates derived from the remaining data would be increased slightly. Since we know that our estimates were lowered because of our inability to measure the early morning, evening and night activity, an increase resulting from the elimination of these low counts would be negligible.

Our monthly use estimates and their totals are presented in Table 1. It is interesting to note that fishing was by far the most important activity, accounting for 70% of the total. This is a minimal figure since we know that a substantial proportion of the boaters, the second largest category, were actually fishermen underway from one fishing ground to another or between fishing grounds and a landing. The monthly air count summaries upon which these estimates are based are presented in Tables 2 through 13. These Tables show the activity by sector for each month. Tables 14, 15 and 16

present the distribution of the three predominant activities, boat fishing, boating and bank fishing, by month and sector of the estuary in the original count form. The data indicate that Great Bay is by far the most popular boat fishing area, with the Lower Mullica River and the Brigantine Wildlife Refuge (actually, the portion of the Intracoastal Waterway which passes through the Refuge) of secondary importance. Bank fishermen preferred Great Bay Boulevard by a substantial margin. The Middle Mullica River was second but one must bear in mind the fact that two-thirds of the activity entered in this category was ice fishing in January. The Lower Mullica ranked third. Great Bay ranked most important in the boating category. Since it is known that a substantial proportion of the boaters are actually fishermen, one would expect a relationship between boat fishing areas and boating.

Our shellfishermen estimate is probably low because much of this activity is carried on at the lower half of the tidal cycle and only about half of our flights could be expected to fall during this period. As would be expected, the data show that this activity was pursued in the Great Bay and Brigantine Refuge sectors.

Waterfowl hunters were found to be difficult to count. Since the prevailing method of hunting involves attracting the birds with decoys to the hidden hunter, the skillful hunter is hidden from aerial observation by man or bird.

The estimated grand total of 129,698 man-days for all kinds of activity is no doubt low for the reasons already mentioned. It probably can be increased by 10 percent with little danger of over-estimating.

While these low estimates might be considered an indication

of serious shortcomings in our method, one must bear in mind the fact that a system designed to measure 'everything' must be a compromise and expected to fall short in some areas. The only alternative would be separate surveys, each of which would be focused on one or perhaps two closely related activities. Every effort will be made to improve our techniques in future surveys.

Harvest Estimates

Creel census results, expanded to the extent of our use estimates, indicate that about a million fish are taken by anglers from the Great Bay-Hullica Estuary in a year's time (Table 17). The catch composition, in terms of the numbers of fish actually censused and in percentages, is presented in Tables 18 and 19 for the boat fishery and the bank fishery, respectively. For boat fishermen, the blowfish made up more than half the total catch, followed by white perch, winter flounder, bluefish and striped bass, in that order. Bank fishermen (including ice fishermen) caught mostly white perch, with winter flounder, blue crabs, and blowfish following in descending order of importance.

Waterfowl hunters averaged about one bird per trip over the entire season. Actually, success was low early in the season, with the highest bird per trip ratio at the end of the season. This is shown by data in Table 20. The September data reflects conditions in 1969, but should not be considered typical. Clapper rail populations were at an extremely low level that year, and in addition, most of the birds moved south because of cool weather immediately after the season opened. The remaining hunting data is considered typical. Table 21 lists the species taken and the importance of each in the hunter's bag.
